

Week 1: OpenClaw Architecture

Thai | IDX Exchange Internship

The goal is to let someone ask about real estate through WhatsApp and get an answer based on the MLS data. OpenClaw connects the conversation to the skills and tools needed to answer the question.

How the parts fit together

Channels bring messages in and send replies back. Here, the channel is WhatsApp.

The runtime runs the request, and the orchestrator selects the right skill.

Skills describe tasks like property search. Tools do the actual work, such as querying MySQL.

Sessions keep each conversation separate. Memory keeps useful context so the user can ask follow-up questions.

Planned workflow

Example

For "3-bedroom condos in Irvine under \$1.5M," the property-search skill would turn the request into filters. The SQL tool would query `rets_property`, and OpenClaw would return the matching homes in a readable reply.

I have imported the data and tested the Python-to-MySQL connection. This diagram shows the planned flow; the full agent response and database integration still need testing.
